

DESCRIPTION

INFORMATION RECORDING AND REPRODUCING
APPARATUS AND A METHOD OF CONTROLLING AN INFORMATION

5 RECORDING AND REPRODUCING APPARATUS

TECHNICAL FIELD

The present invention relates to information
recording and reproducing apparatuses and, more
10 particularly, to an information recording and
reproducing apparatus which performs recording and
reproduction of information on a recordable or
rewritable recording medium having a plurality of
recording layers.

15

BACKGROUND ART

There is an information recording and
reproducing apparatus that performs a so-called
background formatting when, for example, formatting a
20 DVD+RW disc which is a rewritable disc. In the
background formatting, a notification of completion of
formatting is sent to a host computer at a time when
recording is performed on only a part of a lead-in area
of the DVD+RW disc, and a remaining area is recorded by
25 dummy data when there is no access request from the host

computer. According to the background formatting, a formatting process time is greatly reduced.

Additionally, as another feature of the background formatting, there is an advantage that a disk
5 can be ejected in the middle of a formatting process. At that time, in order to enable reproduction by a conventional reproduction only apparatus, when ejecting a disc in a middle of a formatting process, the disc is ejected after filling an unrecorded area of a data area
10 with dummy data and recording a lead-in area and a lead-out area. Thus, logical compatibility of the disc, which is ejected in the middle of the formatting process, with a DVD-ROM can be maintained.

In recent years, a dual-layer DVD+RW disc
15 (DVD+RW DL (Dual Layer) Disc), which has two recording layers, has been developed as a disc on which a large amount of data can be recorded. Accordingly, there has been developed an information recording and reproducing apparatus, which performs recording and reproduction
20 with respect to the dual-layer DVD+RW disc (for example, refer to Japanese Laid-Open Patent Application No. 2004-303421).

The background formatting is also used for the dual-layer DVD+RW disc, similar to the DVD+RW disc
25 having a single recording layer. That is, a part of a

lead-in area is recorded for a request for formatting from a host computer, and a notification of completion of the formatting is sent to the host computer so as to enable an access by the host computer and user data is recorded from a data area of the first layer. Then, while there is no access request from the host computer, remaining areas from the first layer to the second layer are recorded with dummy data. Additionally, eject of the disc in the middle of formatting process is enabled.

10 However, when ejecting the dual-layer DVD+RW disc in the middle of a formatting process, data is recorded in a temporary middle zone (TMZ) immediately after recording end position of user data of the first layer and the data of the temporary middle zone is recorded immediately after a position corresponding to the user data recording end position in a data area of the second layer, and the disc is ejected after filling an unrecorded part of the data area of the second layer with dummy data so as to maintain compatibility with a DVD-ROM.

FIG. 1 and FIG. 2 are illustrations for explaining a process performed when ejecting a dual-layer DVD+RW disc in the middle of a conventional formatting process.

25 As shown in FIG. 1, after recording an initial

zone 50 of a lead-in area, recording instructed by a host computer is permitted. Then, if a request of ejecting the optical disc is made when the user data 51 is recorded, data 52 of a temporary middle zone if
5 recorded from the end of the recorded position of the user data 51 as shown in FIG. 2, and data 53 of the temporary middle zone is recorded immediately after a position corresponding to the above-mentioned user data recording end position in the second layer. Then, an
10 unrecorded area 54 in the second layer is recorded with dummy data, and, thereafter, the lead-in area 55 and the lead-out area 56 are recorded and, then, the optical disc is ejected.

However, in the conventional information
15 recording and reproducing apparatus, if a last recording position of user data or a format end position of a recording medium having a two recording layers, an area in the second layer corresponding to the first recording layer must be recorded with dummy data when a request of
20 ejecting the recording medium is made. Thus, there is a problem that it takes a considerably long time until the recording medium is ejected.

DISCLOSURE OF THE INVENTION

25 It is a general object of the present

invention to provide improved and useful information recording and reproducing apparatus and method in which the above-mentioned problems are eliminate.

A more specific object of the present
5 invention is to provide information recording apparatus and method which can reduce a time to eject a recording medium having a plurality of recording layers in the middle of a formatting process.

In order to achieve the above-mentioned
10 objects, there is provided according to one aspect of the present invention a method for recording information to a recording medium having at least a first recording layer and a second recording layer, the first recording layer having a data area comprising an
15 inner side located at a radially inner region of the recording medium and an outer side located at a radially outer region of the recording medium and the second recording layer comprising a data area including an inner side located at the radially inner region of the
20 recording medium and an outer side located at the radially outer region of the recording medium, the method comprising: performing a first formatting process on the data area of the second recording layer, said first formatting process comprising formatting said data
25 area of the second recording layer in a series of

recording increments, the series of recording increments progressing from the inner side of the data area of the second recording layer to the outer side of the data area of the second recording layer, wherein within each
5 recording increment the formatting is performed along a path extending from the outer side of the data area of the second recording layer to the inner side of the data area of the second recording layer; performing a second formatting process on the data area of the first
10 recording layer once the first formatting process has been completed, the second formatting process being performed along a path extending from the inner side of the data area of the first recording layer to the outer side of the data area of the first recording layer.

15 The recording medium can be a disc-shaped optical recording medium, in which case the radially inner region of the recording medium would be located in the region of the inner periphery of the recording medium, and the radially outer region of the recording
20 medium would be located in the region of the outer periphery of the recording medium. This would also apply to other shapes of recording media.

 The first formatting process could occur when there is no request for user data to be read or
25 recording, and when there is no request for the disk to

be ejected.

In the above aspect, the formatting within each recording increment the formatting is performed along a path extending from the outer side of the data area of the second recording layer to the inner side of the data area of the second recording layer. In other words, the direction of formatting within each recording increment could be from the outer side of to the inner side of the data area of the second recording layer.

As a result of the features of the above aspect of the invention, the time needed to eject the recording medium having a plurality of recording layers can be reduced when ejecting the recording medium in the middle of a formatting process.

The recording medium may adapted to be recorded by a laser, and the first recording layer may be the recording layer closest the laser during use. The second layer could be the layer the next closest to the laser in use.

The recording medium may be associated with an order of recording user data for each recording layer, and the first recording layer may be arranged to be earlier in the recording order than the second recording layer.

In some embodiments, the method further

comprises recording user data on a data area of the first recording layer along a path extending from the inner side of the data area of the first recording layer to the outer side of the data area of the first recording layer on receipt of a request to record user data.

On receiving a request to record user data, the method may comprise recording the user data in priority to the performing the first formatting process or the second formatting process.

The method may further comprise resuming the first formatting process after recording the user data if the first formatting process is not complete. The method may further comprise resuming the second formatting process after recording the user data if the first formatting process is complete.

In some embodiments, the method further comprises: recording predetermined data on the first recording layer at a position immediately after recorded user data on receipt of a request to eject the recording medium.

In some embodiments, the method further comprises: recording predetermined data on the second recording layer at a corresponding radial position to the predetermined data on the first recording layer.

In some embodiments, the method further comprises: recording predetermined data on the second recording layer at the bit inverted addresses to the addresses of the predetermined data on the first
5 recording layer.

On receipt of a request to eject the recording medium, if an end position of the user data on the first recording layer is further in the radially outer direction of the recording medium than an end position
10 of formatted data on the second recording layer, then the method may further comprise: performing a formatting process on the data area of the second recording layer so as to make the radial position of the end position of formatted data on the second recording layer correspond
15 to the radial position of the end position of the user data on the first recording layer.

In some embodiments, the path from the inner side of the data area on the first recording layer to the side of the data area on the first recording layer
20 corresponds to the path from the inner side of the data area on the second recording layer to the side of the data area on the second recording layer. The correspondence could be equivalent radial positions in the recording medium of points in each path. The
25 correspondence could also be that the areas along each

path are at bit-inverted addresses. In such embodiments,
on receipt of a request to eject the recording medium,
if an end position of the user data on the first
recording layer is further along the path from the inner
5 side of the data area on the first recording layer to
the outer side of the data area on the first recording
layer than an end position of formatted data on the
second recording layer, then the method may further
comprise: performing a formatting process on the data
10 area of the second recording layer so as to make the
radial position of the end position of formatted data on
the second recording layer correspond to the radial
position of the end position of the user data on the
first recording layer. Such a formatting process could
15 make the address of the end position of formatted data
on the second recording layer be the bit inverted
address of the address of the end position of the user
data on the first recording layer.

On receipt of a request to eject the recording
20 medium, if an end position of the recording of the user
data on the first recording layer is further in the
radially outer direction of the recording medium than an
end position of formatted data on the second recording
layer, then the method may further comprise: performing
25 a formatting process on the data area of the second

recording layer so as to make the address of the end position of formatted data on the second recording layer be the bit inverted address of the address of the end position of the user data on the first recording layer.

5 On receipt of a request to eject the recording medium, the method may further comprise: obtaining a last recorded position of data on said recording medium; recording, when formatting has been completed to a position of each recording layer corresponding to said
10 last recorded area, predetermined data at a position immediately after said last recorded position in the recording layer having said last recorded position and at a position immediately after a position corresponding to said last recorded position in each recording layer
15 in which the data is not recorded; and ejecting said recording medium after recording the predetermined data.

 On receipt of a request to eject the recording medium, the method may further comprise: obtaining a last recorded position of data on said recording medium;
20 obtaining a format end position of each recording layer in which the data is not recorded yet; recording dummy data, when an area from said last recorded position to a position corresponding to said format end position is an unrecorded area with respect to one of the recording
25 layers having said last recorded position of the data in

accordance with said last recorded position and said format end position, the dummy data being recorded in the area from said last recorded position to the position corresponding to said format end position;

5 recording predetermined data at a position immediately after the recorded dummy data in each recording layer having said last recorded position of the data, at a position immediately after said format end position in the recording layer having said format end position, and
10 at a position corresponding to said format end position in each recording layer in which data is not recorded yet and formatting has completed; and ejecting said recording medium after recording the predetermined data.

The recording medium may be an optical disk.

15 According to a second aspect of the invention, there is provided an information recording apparatus arranged to record data on a recording medium having at least a first recording layer and a second recording layer, the first recording layer having a data area
20 comprising an inner side located at a radially inner region of the recording medium and an outer side located at a radially outer region of the recording medium and the second recording layer comprising a data area including an inner side located at the radially inner
25 region of the recording medium and an outer side located

at the radially outer region of the recording medium,
the apparatus being arranged to: format the data area of
the second recording layer of the recording medium
according to a first formatting process, said first
5 formatting process comprising formatting said data area
of the second recording layer in a series of recording
increments, the series of recording increments
progressing from the inner side of the data area of the
second recording layer to the outer side of the data
10 area of the second recording layer, wherein within each
recording increment the formatting is performed along a
path extending from the outer side of the data area of
the second recording layer to the inner side of the data
area of the second recording layer; format a data area
15 of the first recording layer of the recording medium
according to a second formatting process once the first
formatting process has been completed, the second
formatting process being along a path extending from the
inner side of the data area of the first recording layer
20 to the outer side of the data area of the first
recording layer.

The apparatus may be adapted to record data to
the recording medium using a laser, wherein the first
recording layer is the recording layer closest the laser
25 during use. The second layer could be the layer the next

closest to the laser in use.

The recording medium may be associated with an order of recording user data for each recording layer, and the first recording layer may be arranged to be
5 earlier in the recording order than the second recording layer.

The apparatus may be further arranged to record user data on a data area of the first recording layer along a path extending from the inner side of the
10 data area of the first recording layer to the outer side of the data area of the first recording layer on receipt of a request to record user data.

On receipt of a request to record user data, the apparatus may be further arranged to record the user
15 data in priority to the performing the first formatting process.

The apparatus may be further arranged to resume performing the first formatting process after recording the user data if the first formatting process
20 is not complete.

In some embodiments, the apparatus is further arranged to resume performing the second formatting process after recording the user data if the first formatting process is complete.

25 The apparatus may be further arranged to

record predetermined data on the first recording layer at a position immediately after recorded user data on receipt of a request to eject the recording medium.

The apparatus may be further arranged to
5 record predetermined data on the second recording layer at a corresponding radial position to the predetermined data on the first recording layer.

The apparatus may be further arranged to
record predetermined data on the second recording layer
10 at the bit inverted addresses to the addresses of the predetermined data on the first recording layer.

On receipt of a request to eject the recording medium, if an end position of the recording of the user data on the first recording layer is further in the
15 radially outer direction of the recording medium than an end position of formatted data on the second recording layer, then the apparatus is further arranged to:

format the data area of the second recording layer so as to make the radial position of the end position of
20 formatted data on the second recording layer correspond to the radial position of the end position of the user data on the first recording layer.

On receipt of a request to eject the recording medium, if an end position of the recording of the user
25 data on the first recording layer is further in the

radially outer direction of the recording medium than an end position of formatted data on the second recording layer, then the apparatus is further arranged to: format the data area of the second recording layer so as to
5 make the address of the end position of formatted data on the second recording layer be the bit inverted address to the address of the end position of the user data on the first recording layer.

On receipt of a request to eject the recording
10 medium, the apparatus may be adapted to: obtain a last recorded position of data on said recording medium; record, when formatting has been completed to a position of each recording layer corresponding to said last recorded area, predetermined data at a position
15 immediately after said last recorded position in the recording layer having said last recorded position and at a position immediately after a position corresponding to said last recorded position in each recording layer in which the data is not recorded; and eject said
20 recording medium after recording the predetermined data.

On receipt of a request to eject the recording medium, the apparatus may be adapted to: obtain a last recorded position of data on said recording medium; obtain a format end position of each recording layer in
25 which the data is not recorded yet; record dummy data,

when an area from said last recorded position to a position corresponding to said format end position is an unrecorded area with respect to one of the recording layers having said last recorded position of the data in accordance with said last recorded position and said
5 format end position, the dummy data being recorded in the area from said last recorded position to the position corresponding to said format end position; record predetermined data at a position immediately
10 after the recorded dummy data in each recording layer having said last recorded position of the data, at a position immediately after said format end position in the recording layer having said format end position, and at a position corresponding to said format end position
15 in each recording layer in which data is not recorded yet and formatting has completed; and eject said recording medium after recording the predetermined data.

The recording medium may be an optical disk.

According to a third aspect of the invention,
20 there is provided an information recording and reproducing apparatus configured and arranged to record data on and reproduce data from each of a plurality of recording layers of a recording medium, comprising: a controller that controls a formatting process to format
25 said recording medium by starting from one of the

recording layers of which recording order of data is latest and progressing the formatting from one of the recording layers of which the recording order is later toward one of the recording layers of which the
5 recording order is earlier.

In the information recording and reproducing apparatus according to the present invention the recording medium may be an optical disc, and the controller may control to start the formatting process
10 of each of the recording layers from an inner side of said optical disc.

In the information recording and reproducing apparatus according to the present invention, the controller may control an eject process to eject the
15 recording medium from the information recording and reproducing apparatus so as to obtain a last recorded position of data on the recording medium when an instruction of ejecting said recording medium is made; record, when formatting has been completed to a position
20 of each recording layer corresponding to the last recorded area, predetermined data at a position immediately after the last recorded position in the recording layer having the last recorded position and at a position immediately after a position corresponding to
25 the last recorded position in each recording layer in

which the data is not recorded; and eject the recording medium after recording the predetermined data.

In the information recording and reproducing apparatus according to the present invention, the

5 controller may control an eject process to eject the recording medium from the information recording and reproducing apparatus so as to obtain a last recorded position of data on the recording medium when an

10 instruction of ejecting the recording medium is made; obtain a format end position of each recording layer in which the data is not recorded yet; record dummy data, when an area from the last recorded position to a position corresponding to the format end position is an unrecorded area with respect to one of the recording

15 layers having the last recorded position of the data in accordance with the last recorded position and the format end position, the dummy data being recorded in the area from the last recorded position to the position corresponding to the format end position; record

20 predetermined data at a position immediately after the recorded dummy data in each the recording layer having the last recorded position of the data, at a position immediately after the format end position in the recording layer having the format end position, and at a

25 position corresponding to the format end position in

each recording layer in which data is not recorded yet and formatting has completed; and eject the recording medium after recording the predetermined data.

Additionally, there is provided according to
5 another aspect of the present invention an information recording and reproducing apparatus configured and arranged to record data on and reproduce data from each of a plurality of recording layers of a recording medium, comprising: formatting means for formatting said
10 recording medium by starting from one of the recording layers of which recording order of data is latest and progressing the formatting from one of the recording layers of which the recording order is later toward one of the recording layers of which the recording order is
15 earlier.

In the information recording and reproducing apparatus according to the above-mentioned invention, the recording medium may be an optical disc, and the formatting means may include means for starting the
20 formatting of each of the recording layers from an inner side of said optical disc.

The information recording and reproducing apparatus according to the above-mentioned invention may further comprise: means for obtaining a last recorded
25 position of data on the recording medium when an

instruction of ejecting the recording medium is made;
means for recording, when formatting has been completed
to a position of each recording layer corresponding to
the last recorded area, predetermined data at a position
5 immediately after the last recorded position in the
recording layer having the last recorded position and at
a position immediately after a position corresponding to
the last recorded position in each recording layer in
which the data is not recorded; and means for ejecting
10 the recording medium after recording the predetermined
data.

The information recording and reproducing
apparatus according to the above-mentioned invention may
further comprise: means for obtaining a last recorded
15 position of data on the recording medium when an
instruction of ejecting said recording medium is made;
means for obtaining a format end position of each
recording layer in which the data is not recorded yet;
means for recording dummy data, when an area from the
20 last recorded position to a position corresponding to
the format end position is an unrecorded area with
respect to one of the recording layers having the last
recorded position of the data in accordance with the
last recorded position and the format end position, the
25 dummy data being recorded in the area from the last

recorded position to the position corresponding to the
format end position;

means for recording predetermined data at a
position immediately after the recorded dummy data in
5 each the recording layer having the last recorded
position of the data, at a position immediately after
the format end position in the recording layer having
the format end position, and at a position corresponding
to said format end position in each recording layer in
10 which data is not recorded yet and formatting has
completed; and means for ejecting the recording medium
after recording the predetermined data.

Further, there is provided according to
another aspect of the present invention a method of
15 controlling an information recording and reproducing
apparatus configured and arranged to record data on and
reproduce data from each of a plurality of recording
layers of a recording medium, the method comprising: a
formatting step of formatting the recording medium by
20 starting from one of the recording layers of which
recording order of data is latest and progressing the
formatting from one of the recording layers of which the
recording order is later toward one of the recording
layers of which the recording order is earlier.

25 In the method of controlling an information

recording and reproducing apparatus according to the present invention, the recording medium may be an optical disc, and the formatting step may include a step of starting the formatting of each of the recording
5 layers from an inner side of the optical disc.

The method of controlling an information recording and reproducing apparatus according to the present invention may further comprise: a step of obtaining a last recorded position of data on the
10 recording medium when an instruction of ejecting the recording medium is made; a step of recording, when formatting has been completed to a position of each recording layer corresponding to the last recorded area, predetermined data at a position immediately after the
15 last recorded position in the recording layer having the last recorded position and at a position immediately after a position corresponding to the last recorded position in each recording layer in which the data is not recorded; and a step of ejecting the recording
20 medium after recording the predetermined data.

The method of controlling an information recording and reproducing apparatus according to the present invention may further comprise: a step of obtaining a last recorded position of data on the
25 recording medium when an instruction of ejecting the

recording medium is made; a step of obtaining a format
end position of each recording layer in which the data
is not recorded yet; a step of recording dummy data,
when an area from the last recorded position to a
5 position corresponding to the format end position is an
unrecorded area with respect to one of the recording
layers having the last recorded position of the data in
accordance with the last recorded position and the
format end position, the dummy data being recorded in
10 the area from the last recorded position to the position
corresponding to the format end position; a step of
recording predetermined data at a position immediately
after the recorded dummy data in each the recording
layer having the last recorded position of the data, at
15 a position immediately after the format end position in
the recording layer having the format end position, and
at a position corresponding to the format end position
in each recording layer in which data is not recorded
yet and formatting has completed; and a step of ejecting
20 the recording medium after recording the predetermined
data.

According to the above-mentioned aspects of
the invention, a time spent on ejecting the recording
medium having a plurality of recording layers can be
25 reduced when ejecting the recording medium in the middle

of a formatting process.

Other objects, features and advantages of the present invention will become more apparent from the following detailed description when read in conjunction
5 with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

BEST MODE FOR CARRYING OUT THE INVENTION

A description will now be given, with reference to the drawings, of embodiments according to the present invention.

FIG. 3 is a block diagram of an information recording and reproducing apparatus according to first

through fourth embodiments of the present invention. In FIG. 3, an optical disc 1 is a recording medium having a plurality of recording layers. In the embodiments, the disc 1 is a recordable recording medium having two recording layers that includes a dual-layer DVD+RW disc. The information recording and reproducing apparatus is an optical disc apparatus that performs recording and reproduction with respect to the optical disc 1 having the two recording layers.

10 A spindle motor 2 is a motor for rotating the optical disc 1 at predetermined rotation speeds when recording and reproducing data, respectively. A rotation control part 3 controls rotation of the motor 2. An optical pickup 4 is a device that emits and
15 irradiates a laser light L at a predetermined recording power when recording data on the optical disc 1 or reproducing data from the optical disc 1. An actuator control part 5 controls to move the optical pickup 4 when performing focusing and tracking on the optical
20 disc 1. A signal control part 6 controls a reproduction signal output from the optical pickup 4 and a recording signal output to the optical pickup 4.

 A drive controller 7 is achieved by a microcomputer comprising a CPU, a ROM, a RAM, etc. The
25 drive controller 7 controls the entire information

recording and reproducing apparatus, and also performs a function of means including formatting means according to the present invention. A buffer memory 8 is a memory used as a temporarily storage area that is used by the
5 drive controller 7 to store data. A laser drive circuit 9 drives a laser of the optical pickup 4 to emit the laser light L. An external interface 10 is used for transmitting/receiving commands and data to/from a host computer 11. The host computer 11 incorporates therein
10 a control part that is realized by a microcomputer comprising a CPU, a ROM, a RAM, etc. The host computer 11 is an information processing apparatus such as a personal computer that controls the information recording and reproducing apparatus.

15 (First Embodiment)

In a first embodiment of the present invention, the drive controller 7 controls a formatting process performed on the optical disc 1 so that the formatting process is started from a second layer of which turn of
20 recording is last and the formatting is progressed to a first recording layer of which turn of recording is earlier than the first recording layer.

FIG. 4 is a flowchart of a disc eject process according to the first embodiment of the present
25 invention performed in the information recording and

reproducing apparatus shown in FIG. 3.

Upon receipt of a format command from the host computer 11 in step S1, the drive controller 7 records, in step S2, a zone of a lead-in area of the first recording layer of the optical disc 1, and sends a notification of completion of formatting process to the host computer 1 and receives a disc access request from the host computer 1.

The drive controller 7 determines whether there is a user data recording request from the host computer 1. If it is determined in step S3 that there is a user data recording request from the host computer 1, the routine proceeds to step S10 so as to record user data received from the host computer 1 from a data area of the first recording layer. When the entire data area of the first recording layer has been recorded, recording is performed on a data area of the second recording layer. The data recording in the data area of the first recording layer is performed in a direction from an inner side to an outer side of the optical disc 1, and the data recording in the data area of the second recording layer is performed in a direction from the outer side to the inner side of the optical disc 1. If it is determined, in step S3, that there is no user data recording request, it is determined, in step S4, whether

or not there is a disc eject request from the host computer 1.

If it is determined, in step S4, that there is no disc eject request from the host computer 1, the routine proceeds to step S11 where it is determined whether or not the formatting process of the data area of the second recording layer has been completed. If it is determined, in step S11, that the formatting process of the data area of the second recording layer has been completed, the routine proceeds to step S12. In step S12, a formatting process of the recording area of the first recording layer is started so as to record data in a direction from the inner side to the outer side of the optical disc 1, and the routine returns to step S3. If it is determined in step S11 that the formatting process of the data area of the second recording layer has not been completed, the routine proceeds to step S13. In step S13, a formatting process of the recording area of the second recording layer is started so as to record data in a direction from the outer side to the inner side of the optical disc 1, and the routine returns to step S3. On the other hand, if it is determined in step S4 that there is a disc eject request from the host computer 1, the routine proceeds to step S5 so as to determine whether or not it is in the middle of

formatting (in background). The middle of formatting mentioned here does not mean a state where a formatting process is performed when a determination is made but means a state where a formatting process has not been
5 completed over an entire data area.

If it is determined, in step S5, that it is not in the middle of formatting, the routine proceeds to step S8. In step S8, dummy data is recorded in an unrecorded recording area of the data area and the lead-
10 in area and the lead-out area are recorded. Then, in step S9, the optical disc 1 is ejected, and the process at this time is ended. If it is determined, in step S5, that it is in the middle of formatting, it is determined, in step S6, whether or not it is in the middle of
15 recording of user data. The middle of recording of user data mentioned here does not mean a state where a user data recording is performed when a determination is made but means a state where a user data recording process has not been completed over an entire area which has not
20 been subjected to a formatting process among the data areas.

If it is determined, in step S6, that it is in the middle of the user data recording, the routine proceeds to step S7. In step S7, data of the temporary
25 middle zone (TMZ) is recorded from the last recorded

position of the user data. Then, in step S8, dummy data is recorded in an unrecorded area of the data area and the lead-in area and the lead-out area are recorded.

Then, in step S9, the optical disc 1 is ejected, and the
5 process at this time is ended.

FIGS. 5 through 7 are illustrations for explaining a disc eject process according to the first embodiment of the present invention performed in the information recording and reproducing apparatus shown in
10 FIG. 3.

The optical disc 1 comprises a first recording layer 20 and a second recording layer 21 as shown in FIG. 5. The first recording layer 20 includes a lead-in area 22, a data area 23 and a middle zone 24 arranged in that
15 order from an inner side toward an outer side of the optical disc 1. The second recording layer 21 includes a middle zone 25, a data area 26 and a lead-out area 27 arranged in that order from the outer side toward the inner side of the optical disc 1. In FIG. 5, the lead-
20 in area 22 and the lead-out area 27, the data areas 26 and 23, and the middle zones 25 and 24 are located in the same radial positions of the optical disc 1, respectively.

That is, the start address of the lead-in area
25 22 and the end address of the lead-out area 27, and the

end address of the lead-in area 22 and the start address of the lead-out area 27 are in the same radial position of the optical disc 1, respectively. Similarly, the start address of the data area 23 and the end address of the data area 26, and the end address of the data area 23 and the start address of the data area 26 are in the same radial positions, respectively. The start address of the middle zone 24 and the end address of the middle zone 25, and the end address of the middle zone 24 and the end address of the middle zone 25 are in the same radial positions, respectively. The above-mentioned corresponding start addresses and end addresses are at bit inversion values, respectively. It will be appreciated that in an optical disc such as that shown in the figures, two addresses at corresponding radial positions on different recording layers of the disc will be bit inverted with respect to each other. Therefore, it will be appreciated that all references to areas on recording areas on different layers having corresponding radial positions also refer to the areas having bit-inverted addresses.

Upon receipt of a format command from the host computer 11 after the optical disc 1 is loaded, the drive controller 7 records an initial zone 30 of the lead-in area 22. After completion of the recording, the

drive controller 7 sends a notification of completion of the formatting to the host computer 11, and, then, receives a disc access for recording or reproduction from the host computer while performing a formatting process of the data areas 23 and 26 at a time when there is no access from the host computer 11. Upon reception of the disc access, the drive controller 7 determines whether or not there is a request of recording user data from the host computer 11. If there is a request of recording user data, recording of user data is performed from the inner side toward the outer side of the data area 23 of the first recording layer.

On the other hand, if there is no request for recording user data, the drive controller determines whether or not there is a request for ejecting the disc. If there is no request for ejecting the disc, the drive controller 7 determines whether or not a formatting process of the second recording layer 21 of the optical disc 1 has been completed with reference to a bitmap recorded in the lead-in area 22. If the formatting process of the second recording layer 21 has not been completed yet, the drive controller 7 starts the formatting process of the data area 26 of the second recording layer 21 from the outer side and continues the formatting process toward the inner side of the optical

disc 1.

On the other hand if the formatting process of the second recording layer 21 has been completed, a formatting process of the first recording layer 20 is performed. Here, if user data is not recorded in the data area 23 of the first recording layer 20, the formatting process is started from the start address on the inner side of the data area 23 and continues the formatting process toward the end address on the outer side of the data area 23. If the user data is recorded in a part of the data area 23, the formatting process is started at the last recording position of the user data and continues the formatting process toward the end address.

Then, when a request for ejecting the optical disc 1 out of the host computer 11 is made, and if only the area 31 of the second recording layer 21 is formatted and the formatting is still continuing and user data has been recorded in an area 32 of the first recording layer 20 as shown in FIG. 6, the last recorded position of the user data in the data area 23 and the end position of the formatting in the data area 26 are obtained so as to record data of TMZ in an area 33 immediately after the area 32 of the first recording layer 20 and record data of TMZ in an area 34 in the

second recording layer 21. Further, dummy data is recorded in an unrecorded area 35 in the second recording layer 21, and the read-in area 22 and the lead-out area 27 are recorded, and, thereafter, the optical disc 1 is ejected. In other embodiments, only data of TMZ in an area 33 immediately after the area 32 of the first recording layer 20 is recorded, and no data of TMZ is recorded in the second recording layer 21.

As mentioned above, by performing the formatting process of the optical disc from the second recording layer of which recording order of user data is later, a time spent on ejecting the optical disc, when a request for ejecting the optical disc is made in the middle of formatting of in the middle of recording user data, can be shortened, thereby reducing a time for ejecting the optical disc.

(Second Embodiment)

A description will be given of a second embodiment of the present invention.

In the second embodiment, the drive controller 7 controls the formatting process of each of the recording layers 20 and 21 of the optical disc 1 to be started from the inner side. FIG. 8 is a flowchart of a disc eject process according to the second embodiment of the present invention performed in the information

recording and reproducing apparatus shown in FIG. 3.

Upon receipt of a format command from the host computer 11 after the optical disc 1 is loaded in step S21, the drive controller 7 records, in step S22, an
5 initial zone of the lead-in area of the first recording layer of the optical disc 1. After completion of the recording, the drive controller 7 sends a notification of completion of the formatting to the host computer 11, and, then, receives a request of accessing a disc for
10 recording or reproduction from the host computer 11.

Then, the drive controller 7 determines, in step S23, whether or not there is a request of recording user data from the host computer 11. If there is a request of recording user data, recording of user data
15 received from the host computer 11 is performed, in step S30, from the data area of the first recording layer 20. After the data area of the first recording layer 20 is recorded, the user data is recorded in the data area of the second recording layer 21.

20 On the other hand, if it is determined, in step S23, that there is no request for recording user data, the drive controller 7 determines, in step S24, whether or not there is a request for ejecting the disc. If it is determined, in step S24, that there is no
25 request for ejecting the disc, the drive controller 7

determines, in step S31, whether or not a formatting process of the second recording layer 21 of the optical disc 1 has been completed.

5 If it is determined, in step S31, that the formatting process of the data area of the second recording layer has been completed, the routine proceeds to step S32. In step S32, a formatting process of the recording area of the first recording layer is started so as to record data in a direction from the inner side
10 to the outer side of the optical disc 1, and the routine returns to step S23.

If it is determined in step S31 that the formatting process of the data area of the second recording layer has not been completed, the routine
15 proceeds to step S33. In step S33, a formatting process of the recording area of the second recording layer is started so as to record data in a direction from the outer side to the inner side of the optical disc 1 by a predetermined amount of data, and the routine returns to
20 step S33. The predetermined amount of data is a previously set recording unit, and the data is recorded from the outer side to the inner side by the recording unit. That is to say that in step S33, the formatting process on the recording area of the second recording
25 layer is performed in recording increments. Within each

recording increment, the formatting is performed along a path from the outer side to the inner side of the recording area of the second recording layer, and the recording increments are along a path from the inner
5 side to the outer side of the recording area.

On the other hand, if it is determined in step S24 that there is a disc eject request from the host computer 11, the routine proceeds to step S25 so as to determine whether or not it is in the middle of
10 formatting (in background). The middle of formatting mentioned here does not mean a state where a formatting process is performed when a determination is made but means a state where a formatting process has not been completed over an entire data area. If it is determined,
15 in step S25, that it is not in the middle of formatting, the routine proceeds to step S28. In step S28, the lead-in area and the lead-out area are recorded. Then, in step S29, the optical disc 1 is ejected, and the process at this time is ended.

20 If it is determined, in step S25, that it is in the middle of formatting, it is determined, in step S26, whether or not it is in the middle of recording of user data. The middle of recording of user data mentioned here does not mean a state where a user data
25 recording is performed when a determination is made but

means a state where a user data recording process has not been completed over an entire area which has not been subjected to a formatting process among the data areas. If it is determined, in step S26, that it is not
5 in the middle of the user data recording, the routine proceeds to step S28. In step S28, the lead-in area and the lead-out area are recorded. Then, in step S29, the optical disc 1 is ejected, and the process at this time is ended.

10 If it is determined, in step S26, that it is in the middle of the user data recording, the routine proceeds to step S27. In step S27, data of the temporary middle zone (TMZ) is recorded from the last recorded position of the user data. Then, in step S28,
15 the lead-in area and the lead-out area are recorded. Then, in step S29, the optical disc 1 is ejected, and the process at this time is ended.

FIG. 9 and FIG. 10 are illustrations for explaining a disc eject process according to the second
20 embodiment of the present invention in the information recording and reproducing apparatus shown in FIG. 3. In FIGS. 9 and 10, parts that are the same as the parts shown in FIGS. 6 through 8 are given the same reference numerals, and description thereof will be omitted.

25 Upon receipt of a format command from the host

computer 11 after the optical disc 1 is loaded, the drive controller 7 records an initial zone 30 of the lead-in area 22 as shown in FIG. 9. After completion of the recording, the drive controller 7 sends a
5 notification of completion of the formatting to the host computer 11, and, then, receives a disc access for recording or reproduction from the host computer 11 while performing a formatting process of the data areas 23 and 26 at a time when there is no access from the
10 host computer 11. Upon reception of the disc access, the drive controller 7 determines whether or not there is a request of recording user data from the host computer 11. If there is a request of recording user data, recording of user data is performed from the inner
15 side toward the outer side of the data area 23 of the first recording layer.

On the other hand, if there is no request for recording user data, the drive controller 7 determines whether or not there is a request for ejecting the disc.
20 If there is no request for ejecting the disc, the drive controller 7 determines whether or not a formatting process of the second recording layer 21 of the optical disc 1 has been completed with reference to a bitmap recorded in the lead-in area 22. If the formatting
25 process of the second recording layer 21 has not been

completed yet, the drive controller 7 starts the formatting process of the data area 26 of the second recording layer 21 sequentially in an order of an area 36 and an area of 37, which have the same amount of data, from the outer side and continues the formatting process toward the inner side of the optical disc 1. It should be noted that the formatting process is progressed in each of the area 36 and the area 37 in a direction from the outer side toward the inner side.

On the other hand, if the formatting process of the second recording layer 21 has been completed, a formatting process of the first recording layer 20 is performed in the same manner as mentioned above. Here, if user data is not recorded in the data area 23 of the first recording layer 20, the formatting process is started from the start address on the inner side of the data area 23 and the formatting process is progressed toward the end address on the outer side of the data area 23. If the user data is recorded in a part of the data area 23, the formatting process is started at the last recording position of the user data and the formatting process is progressed toward the end address.

Then, when a request for ejecting the optical disc 1 out of the host computer 11 is made, and if only the areas 36 and 37 of the second recording layer 21 are

formatted and the formatting is still continuing and user data has been recorded in an area 38 of the first recording layer 20 and if the last recorded position of the user data and the format end position are at the same radial position of the optical disc as shown in FIG. 10, the last recorded position of the user data in the data area 23 and the end position of the formatting in the data area 26 are obtained. Then, if it is determined that both are at the same radial position, data of TMZ is recorded in an area 39 immediately after the area 38 of the first recording layer 20 and data of TMZ is recorded in an area 40 in the second recording layer 21. It should be noted that the area 39 and the area 40 are at the same radial position. It also should be noted that the addresses of area 39 and the area 40 are bit-inverted with respect to each other. Then, the read-in area 22 and the lead-out area 27 are recorded, and, thereafter, the optical disc 1 is ejected. In other embodiments, data of TMZ is recorded in an area 39 immediately after the area 38 of the first recording layer 20, but no data of TMZ is recorded in the second recording layer 21.

As mentioned above, since the user data is recorded from the inner side of the first recording layer, there is no need to format the entire area of the

first and second recording layers if an amount of user data to be recorded is small, and, thereby a time until the optical disc is ejected can be reduced.

(Third Embodiment)

5 A description will now be given of a third embodiment of the present invention.

 In the third embodiment, the drive controller 7 obtains the last recorded position of the first recording layer of the optical disc 1 in which data has
10 been recorded when an instruction to eject the optical disc 1 is made by the host computer 11. Then, if the drive controller 7 determines that the formatting in the second recording layer has been completed to a position corresponding to the above-mentioned last recorded
15 position, the drive controller 7 controls to eject the optical disc 1 after recording TMZ (corresponding to predetermined data) at a position immediately after the last recorded position in the first recording layer which has the above-mentioned last recorded position,
20 and at a position immediately after the position corresponding to the last recorded position in the second recording layer in which the data has not been recorded.

 FIG. 11 is a flowchart of a disc eject process
25 according to the third embodiment of the present

invention performed in the information recording and reproducing apparatus shown in FIG. 3.

The drive controller 7 determines, in step S41, whether or not there is a disc eject request issued from the host computer 11. If there is no disc eject request, the process is ended. If there is a disc eject request, the drive controller 7 controls, in step S42, to record TMZ in the data area of the first recording layer from the last recorded position, and also record TMZ in the second recording layer at a position corresponding to the position where the TMZ is recorded in the first recording layer, and record the lead-in area and the lead-out area. In other embodiments, a TMZ only needs to be recorded on the first recording layer, and no TMZ is recorded in the second recording layer. Then, the drive controller 7 controls, in step S43, to eject the optical disc 1, and ends the process at this time.

FIGS. 12 through 14 are illustrations for explaining the disc eject process according to the third embodiment of the present invention performed in the information recording and reproducing apparatus shown in FIG. 3. In FIGS. 12 through 14, parts that are the same as the parts shown in FIGS. 5 through 7 are given the same reference numerals, and descriptions thereof will be omitted.

If a formatting process of the second recording layer 21 has not been completed yet, the drive controller 7 controls to perform the formatting process on an area 41, an area 42 and an area 43, each of which
5 has the same predetermined capacity and arranged in that order in the data area 26 of the second recording layer 21, sequentially from the inner side toward the outer side as shown in FIG. 12. The areas 41, 42 and 43 are recording increments. The direction of progressing the
10 formatting process in each of the areas 41 to 43 is from the outer side toward the inner side.

Then, when a request of ejecting the optical disc 1 is issued by the host computer 11, the user data last recorded position in the data area 23 and the
15 format end position in the data area 26 are obtained if only the areas 41 through 43 have been formatted and the formatting of the second recording layer 21 has not been completed yet as shown in FIG. 13, the user data is recorded in an area 44 of the first recording layer 20,
20 the user data last recorded position and the format end position are at different positions along a radial direction and an area at the position corresponding to the area 44 in the first recording layer 20 in a radial direction has been formatted. It will be appreciated
25 that if the user data last recorded position and the

format end position are at different positions along a radial direction, then they will not be at bit-inverted addresses. Then, if the drive controller 7 determines that the formatting process has been progressed to the position corresponding to the area 44 in the data area 26 in accordance with the both positions, the drive controller 7 controls to record data of TMZ in an area 45 immediately after the area 44 of the first recording layer 20 and also record data of TMZ in an area 46 of the second recording layer 21. The area 45 and the area 46 are at the same position along a radial direction of the optical disc 1 (i.e. at bit-inverted addressed), and, thus, the area 46 is overwritten on the formatted area. In other embodiments, a TMZ need not be recorded in an area 46 of the second recording layer 21. Then, the lead-in area 22 and the lead-out area 27 are recorded, and the optical disc 1 is ejected.

As mentioned above, when a request of ejecting an optical disc is issued to the information recording and reproducing apparatus, and if the format end position of the second recording layer is on the outer side than the user data last recorded position of the first recording layer 1, there is no need to perform dummy data recording from the user data last recorded position of the first recording layer to the formatting

start position of the second recording layer, thereby reducing a time to eject the optical disc.

(Fourth Embodiment)

A description will now be given of a fourth
5 embodiment of the present invention.

In the fourth embodiment, when an instruction of ejecting the optical disc 1 is issued by the host computer 11, the drive controller 7 obtains the last recorded position in the first recording layer 20 of the
10 optical disc 1 in which data is recorded, and also obtains the format end position in the second recording layer in which data is not recorded. Then, if the drive controller 7 determines that an area of the first recording layer from the above-mentioned last recorded
15 position to the above-mentioned format end position is an unrecorded area with respect to the first recording layer having the above-mentioned last recorded position, the drive controller 7 controls to record dummy data in the area from the above-mentioned last recorded position
20 to the above-mentioned format end position with respect to the first recording layer having the last recorded position, and, record TMZ (corresponding to predetermined data) immediately after the recorded dummy data in the first recording layer and immediately after
25 the format end position in the second recording layer,

and, thereafter eject the optical disc 1.

FIG. 15 is a flowchart of a disc eject process according to the fourth embodiment of the present invention performed in the information recording and
5 reproducing apparatus shown in FIG. 3.

The drive controller 7 determines, in step S51, whether or not there is a disc eject request issued from the host computer 11. If there is no disc eject request, then, the process at this time is ended. If there is a
10 disc eject request, the drive controller 7 determines, in step S52, whether or not a difference between the user data last recorded position in the first recording area and the format end position in the second recording layer is equal to or greater than a predetermined value.
15 The predetermined value is preferably set to, for example, 4,400 sectors which correspond to the length of the middle zone.

If it is determined, in step S52, that the difference between the user data end recorded position
20 and the format end position is equal to or greater than the predetermined value, TMZ is recorded, in step S53, from the user data last recorded position in the data area of the first recording layer, and the lead-in area and the lead-out area are recorded. Then, the optical
25 disc 1 is ejected in step S56, and, then, the process at

this time is ended.

If it is determined, in step S52, that the difference between the user data end recorded position and the format end position is not equal to or greater than the predetermined value (less than the predetermined value), the routine proceeds to step S54. In step S54, dummy data is recorded in a recording area of a range from the user data last recorded position in the data area of the first recording layer to a position corresponding to the format end position of the data area of the second recording layer (a position in the first recording layer at the same position in a radial direction as the format end position of the second recording layer, i.e. at the bit-inverted address). Then, in step S55, TMZ is recorded and the lead-in area and the lead-out area are recorded. Thereafter, the optical disc 1 is ejected in step S56, and the process at this time is ended. In S55, the TMZ could be recorded only the data area of the first recording or on the data areas of both the first and second recording layers.

FIG. 16 is an illustration for explaining the disc eject process according to the fourth embodiment of the present invention performed in the information recording and reproducing apparatus shown in FIG. 3. In FIG. 16, parts that are the same as the parts shown in

FIGS. 12 through 14 are given the same reference numerals, and descriptions thereof will be omitted.

The user data last recorded position in the data area 23 and the format end position in the data area 26 are obtained if only the areas 41 through 43 of the second recording layer 21 have been formatted and the user data is recorded in the area 44 of the first recording layer 20 and the user data last recorded position and the format end position are at different positions along a radial direction and an area at the position corresponding to the area 44 in the first recording layer 20 in a radial direction has been formatted. Then, the drive controller 7 compares the both positions and if it is determined that an unrecorded area 47 corresponding to a difference therebetween is less than the length of the middle zone (for example, 4,400 sectors), the drive controller 7 controls to record dummy data in the unrecorded area 47 and also records the data of TMZ in an area 48 immediately after the unrecorded area 47 and an area 49 immediately before the recording area 43 of the second recording layer 21. Then, after the lead-in area 22 and the lead-out area 27 are recorded, the optical disc 1 is ejected.

On the other hand, if the drive controller 7

determines that the unrecorded area 47 is equal to or longer than the length of the middle zone, the data of TMZ is recorded in the area immediately after the area 44 of the first recording layer 21 and the area of the same position in a radial direction in the second recording layer 21, and the lead-in area 22 and the lead-out area 27 are recorded, and the optical disc 1 is ejected.

It should be noted that, in the above-mentioned process, if it is determined that the length of the formatted area (areas 41 to 43) is shorter than the length of the area 44 already recorded in the data area 23 based on the user data last recorded position in the data area 23 and the format end position of the data area 26, dummy data may be recorded in the unrecorded area 47 corresponding to the difference between the user data last recorded position in the data area 23 and the position in the first recording layer 20 corresponding to the format end position, and the data of TMZ is recorded in the area 49 immediately before the recording area 43 of the second recording layer 21, and the lead-in area 22 and the lead-out area 27 are recorded and, thereafter, the optical disc 1 is ejected.

As mentioned above, if the format end position of the second recording layer and the user data last

recorded position of the first recording layer are not at the same position along a radial direction of the optical disc 1, the unrecorded area of the first recording area is caused to be already recorded in response to the formatted area of the second recording layer. Thus, the formatted area of the second recording layer can be recognized as an already formatted area even after the optical disc is ejected, and, thereby, the formatting process of the second recording layer is not be wasted.

It should be noted that the data of the temporary middle zone (TMZ) recorded when ejecting the dual-layer DVD+RW disc in the above-mentioned embodiments may be dummy data.

Additionally, although the case of the optical disc having two recording layers was explained in the above embodiments, the present invention is applicable to an optical disc having more than two recording layers in the same manner.

The information recording and reproducing apparatus according to the present invention is used with a recording medium having a plurality of recording layers that is detachably attached thereto, and the present invention is applicable to an apparatus that performs recording and reproduction on such as recording

medium.

The present invention is not limited to the specifically disclosed embodiments, and variations and modifications may be made without departing from the
5 scope of the present invention.

The present application is based on Japanese priority application No. 2005-071456 filed March 14, 2005, the entire contents of which are hereby incorporated herein by reference.
